

Low-Level Analysis of High-Density Oligonucleotide Microarray Data

Ben Bolstad

<http://www.stat.berkeley.edu/~bolstad>

Biostatistics, University of California, Berkeley

University of Maryland Baltimore County

Mar 10, 2004

Outline

- What is Low-Level Analysis?
- Affymetrix GeneChip Technology
- Two topics in Low-level analysis
 - Constructing a gene expression measure
 - Probe level models for detecting differential expression

Low-Level Analysis

- What is low-level analysis?
 - Analysis and manipulation of probe intensity data
 - Expression calculation: Background, Normalization, Summarization
 - Determining presence/absence
 - Quality control diagnostics
- Why do we do it?
 - Hopefully it will allow us to produce better, more biologically meaningful gene expression values
 - We want accurate (low bias) and precise (low variance) gene expression estimates
 - Is there additional information at the probe-level that we might otherwise throw away?

High-Level Analysis

- Clustering/Classification
- Pathway Analysis
- Cell Cycle
- Gene function
- Anything where a more biological interpretation is desired

Such matters will not be discussed further in today's talk.

From Chip To Data

Brief Technology Overview

- High density oligonucleotide array technology as developed by Affymetrix
<http://www.affymetrix.com>
- Known as the GeneChip

Probes and Probesets

Two Probe Types

PM: the Perfect Match

MM: the Mismatch differing from the Perfect Match only at the central base

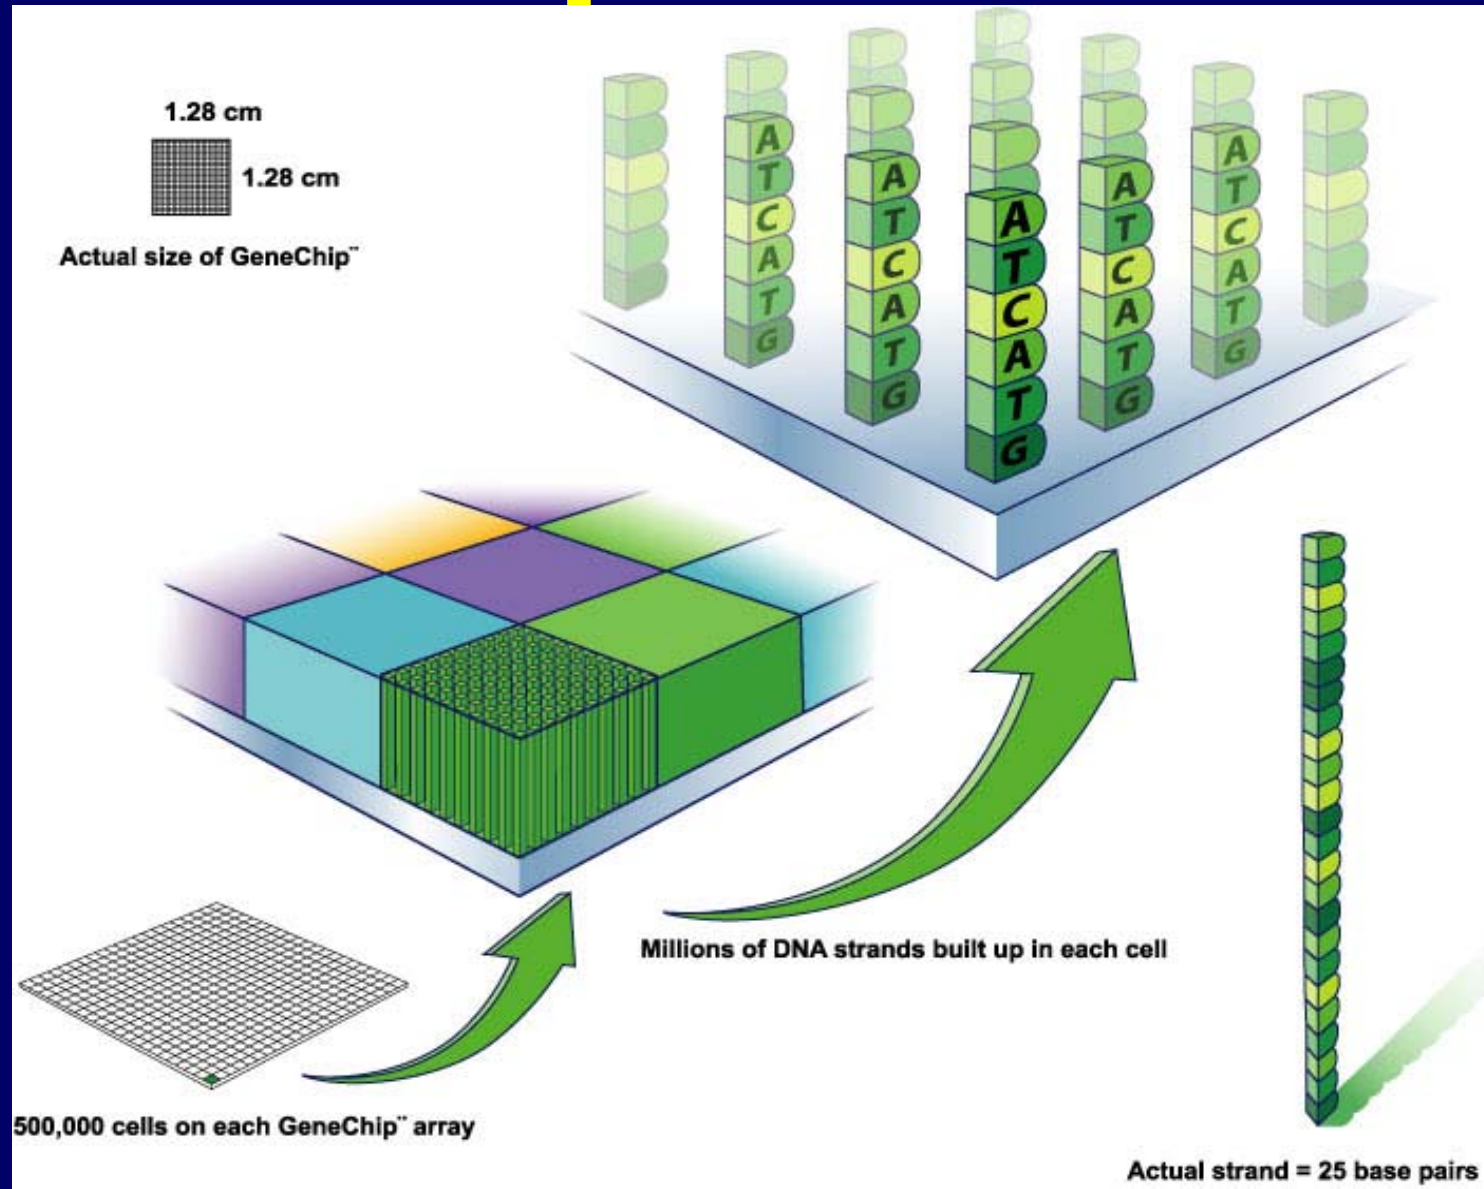

PM: CAGACATAGTGT**C**TGTGTTTCTTCT

MM: CAGACATAGTGT**G**TGTGTTTCTTCT

Constructing the Chip

Focusing on a Single GeneChip Cell Location

Sample Preparation

Hybridization to the Chip

The Chip is Scanned

Constructing a gene expression measure

Computing Expression Measures: A Three Step Procedure

1. Background/Signal adjustment (B)
2. Normalization (N)
3. Summarization (S)

Let X be cel file data from multiple arrays then
Expression values = $S(N(B(X)))$

Background/Signal Adjustment

- A method which does some or all of the following
 - Corrects for background noise, processing effects
 - Adjusts for cross hybridization
 - Adjust estimated expression values to fall on proper scale
- Probe intensities are used in background adjustment to compute correction (unlike cDNA arrays where area surrounding spot might be used)

Background Methods

- Affymetrix
 - Location dependent
 - Ideal mismatch

- RMA
 - Convolution model

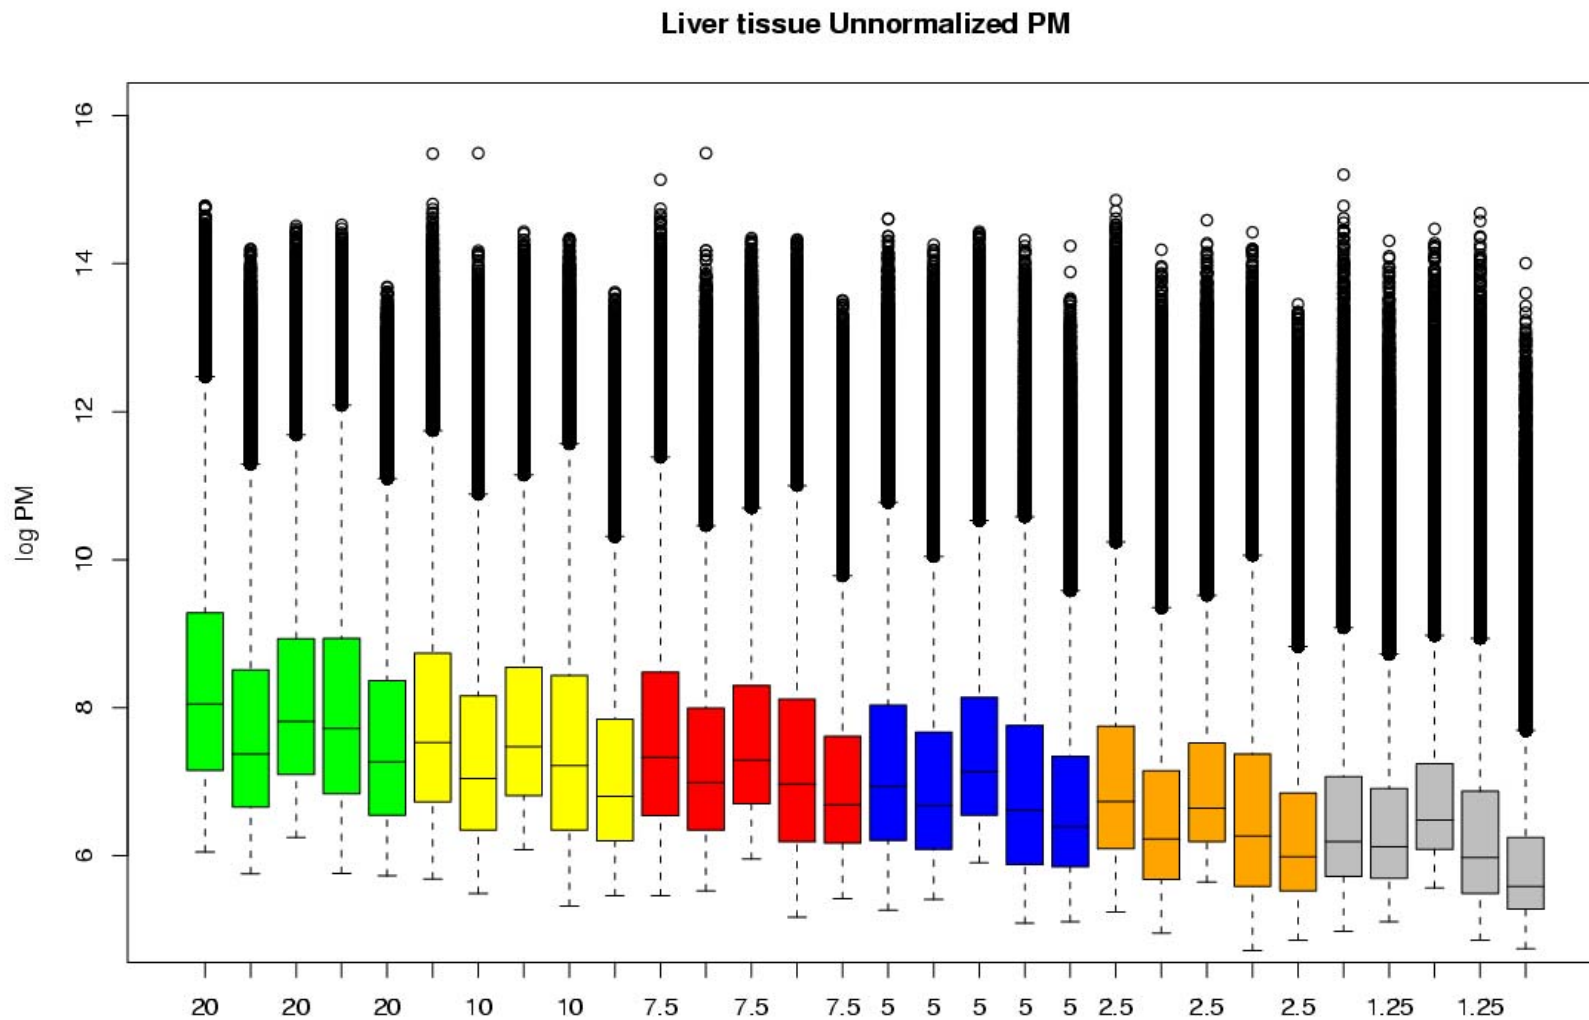

- Other
 - Standard curve adjustment
 - GCRMA (Wu, Irizzary et al 2003)

Normalization

“Non-biological factors can contribute to the variability of data ... In order to reliably compare data from multiple probe arrays, differences of non-biological origin must be minimized.”¹

- Normalization is a process of reducing unwanted variation across chips. It may use information from multiple chips

Non-biological variability

Normalization Methods

- Methods already compared in Bolstad et al (2003)
- Baseline (normalized using reference chip)
 - Scaling (Affymetrix)
 - Non linear (Li-Wong)
- Complete data (no reference chip, information from all arrays used)
 - Quantile normalization (Bolstad et al 2003)
 - Contrast (Åstrand, 2003)
 - Cyclic Loess

Summarization

- Reduce the 11-20 probe intensities for each probeset on each array to a single number for gene expression
- Main Approaches
 - Single chip
 - AvDiff (Affymetrix) – no longer recommended for use due to many flaws
 - Mas 5.0 (Affymetrix) – use a 1 step Tukey biweight to combine the probe intensities in log scale
 - Multiple Chip
 - MBEI (Li-Wong dChip) – a multiplicative model
 - RMA – a robust multi-chip linear model fit on the log scale

Parallel Behaviour Suggests Multi-chip Model

The three steps of RMA

1. Convolution Background
 2. Quantile Normalization
 3. Linear model on the log₂ scale fit robustly.
- Software for implementing RMA is in the Bioconductor *affy* package

Affymetrix Spike-in Data

- 59 chips. All but 1 of the rows are done as triplicates

	37777	684	1597	38734	39058	36311	36889	1024	36202	36085	40322	407	1091	1708

T	1024	0	0.25	0.5	1	2	4	8	16	32	64	1024	256	512

Comparing the background methods

- Using an Affymetrix spike-in experiment we shall examine
 - Observed vs spike-in concentration
 - Observed vs expected fold change
 - Composite M vs A plots
 - ROC curves
- In each case we will compute expression values use standard RMA methodology. (ie quantile normalization, median polish summarization)

Assessing Bias: Observed Expression vs Spike-in Concentration

Slope	None	RMA	MAS 5	IMM	MAS5/ IMM	S.C.A.
All	0.493	0.63	0.589	0.69	0.695	0.856
Mid	0.665	0.784	0.751	0.82	0.82	1.041
Low	0.184	0.376	0.318	0.52	0.563	0.631
High	0.329	0.33	0.327	0.295	0.291	0.256

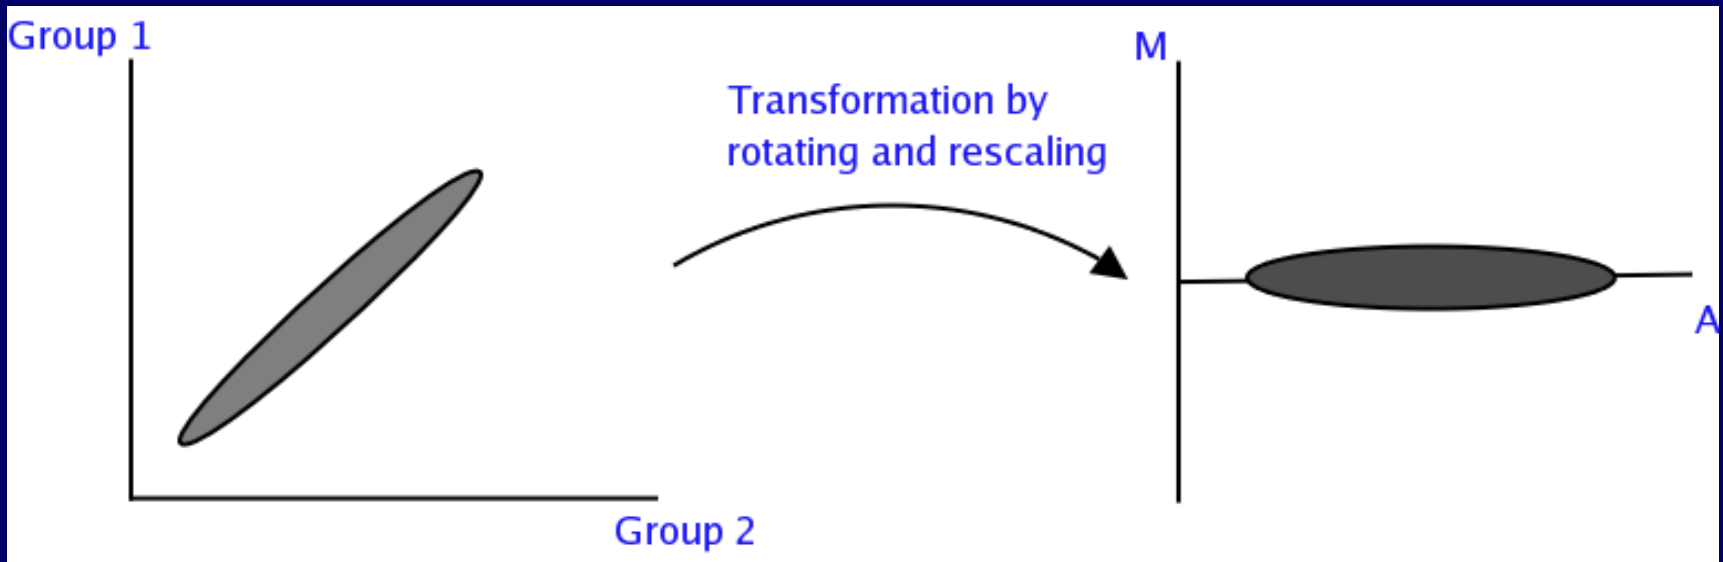

Assessing Bias: Observed Fold-change versus Expected Fold-change

Slope	None	RMA	MAS 5	IMM	MAS5/ IMM	S.C.A.
All	0.484	0.624	0.583	0.683	0.692	0.847

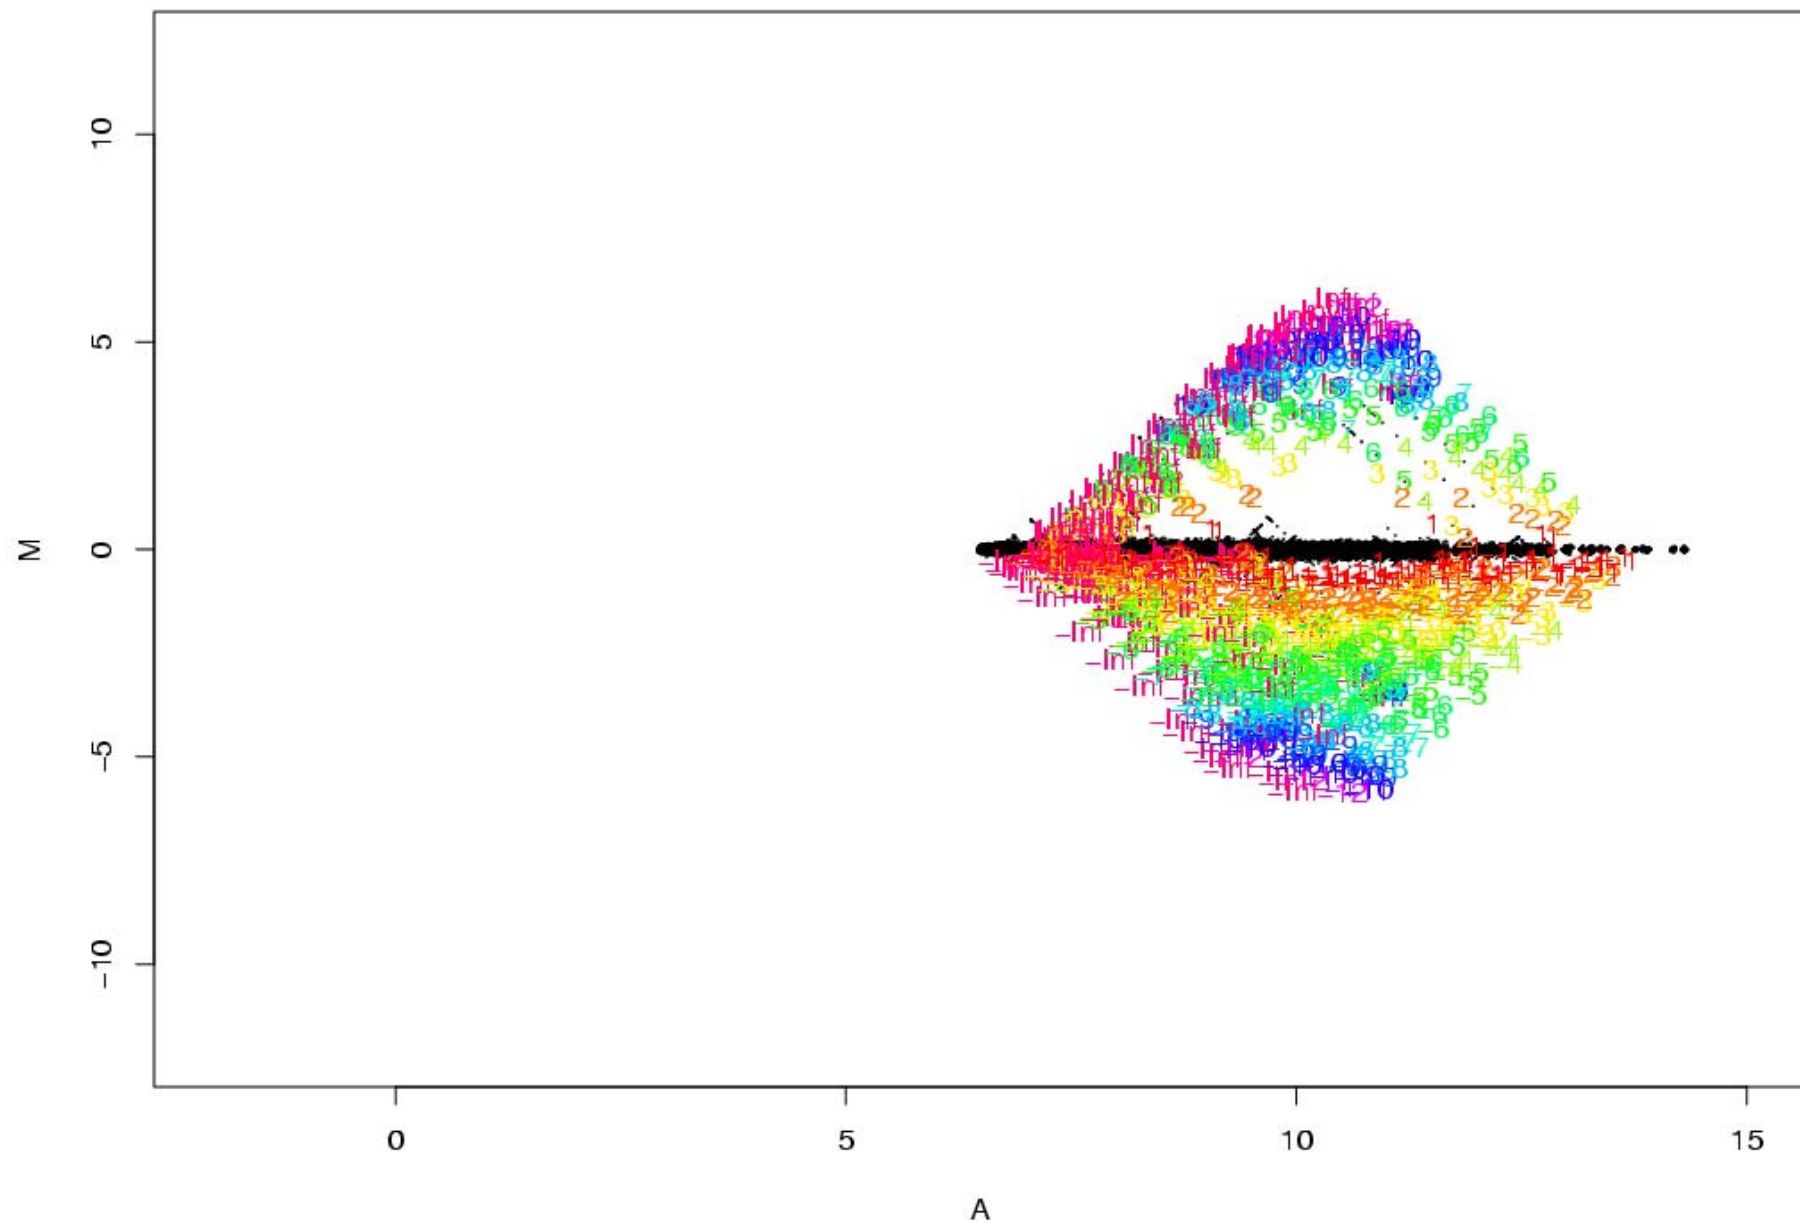

Assessing Variability: M vs A plots

- Vertical Axis is M: \log_2 fold-change.
- Horizontal Axis is A: average expression value (on \log_2 scale) aka geometric average.
- Ideally non differential genes tight about $M=0$

No background

RMA convolution background

MAS 5 background

Ideal Mismatch

Mas5/Ideal Mismatch

Standard Curve Adjustment

Detecting Differential Expression: ROC Curves

Summary of Trade-offs

Background Method	Detect Differential Genes	Accurate estimates of Fold change
No Background	Good	Poor
RMA	Good	Poor
MAS 5.0	Good	Poor
Ideal Mismatch	Poor	Good
MAS5.0/IdealIMM	Poor	Good
Standard Curve Adjustment	Good	Good

Comparing the Normalization Methods

- Want to reduce variation but at the same time we do not want to introduce any bias
- First a quick examination of the expression values by array
- Using same spike-in experiment as before, this time no background correction, only normalization and median polish summarization.

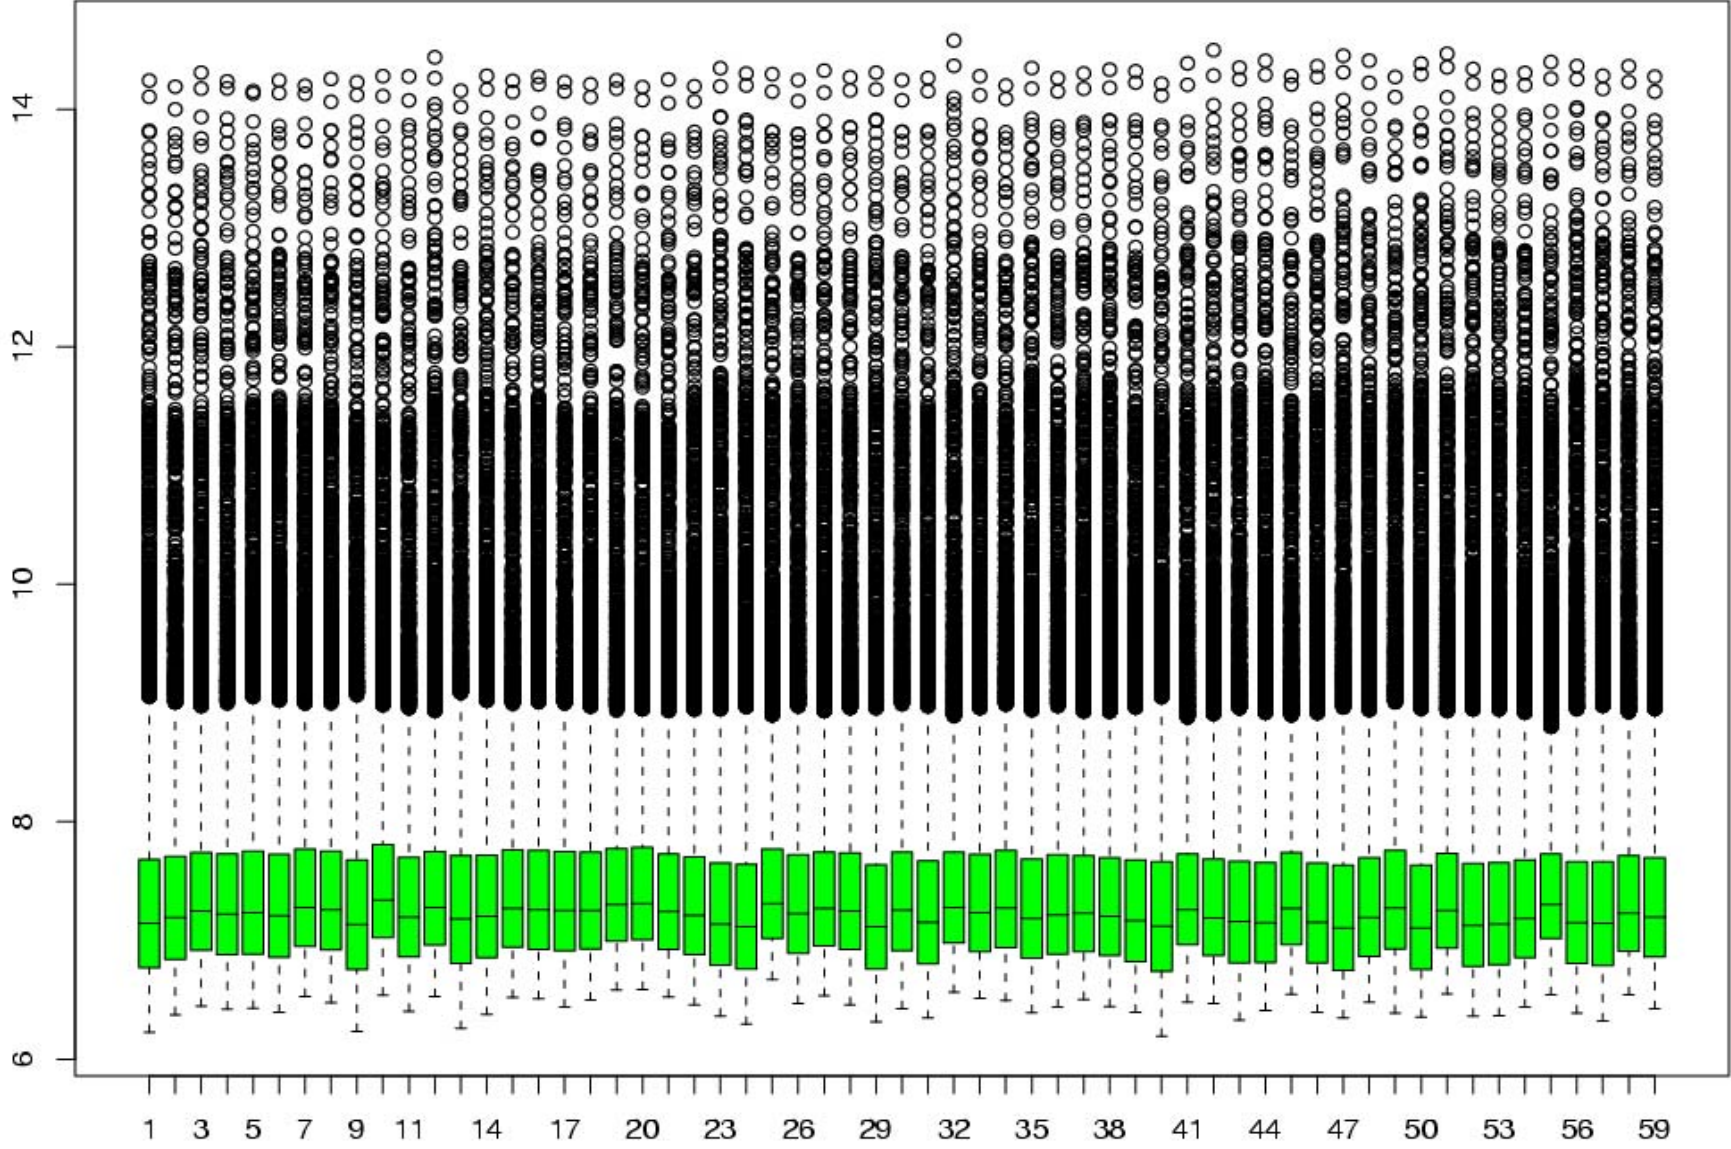

No Normalization

Quantiles

Scaling

Scaling is Not Sufficient

(a) Unnormalized

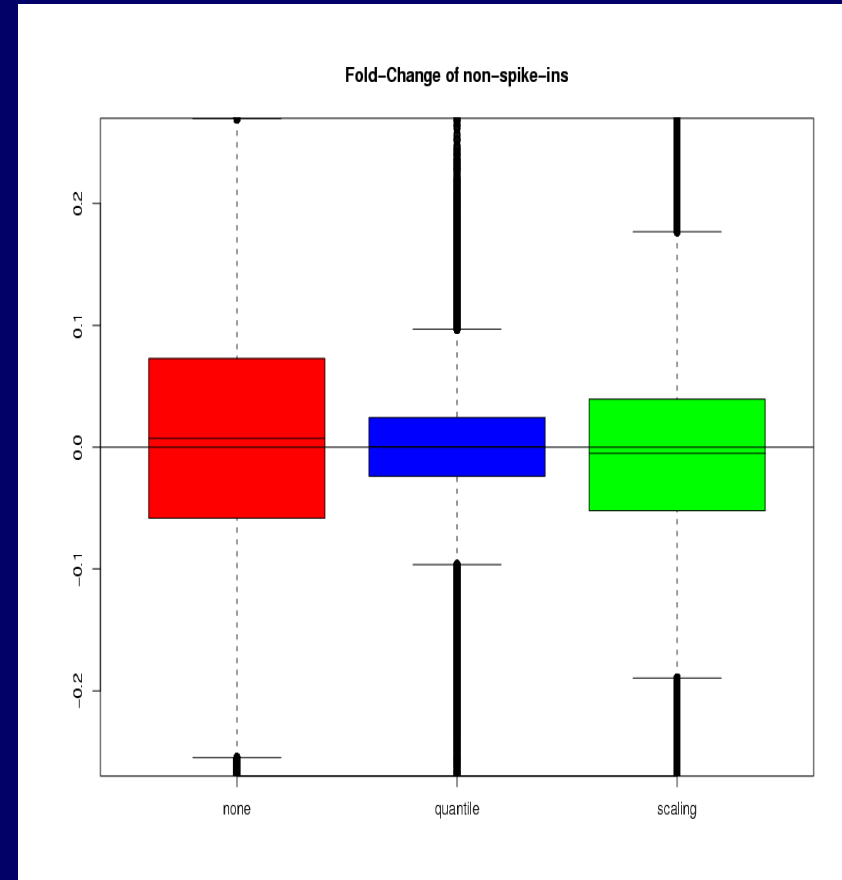

(b) Scaling

(c) Quantile Normalized

Variability of Non-Differential Genes is Reduced

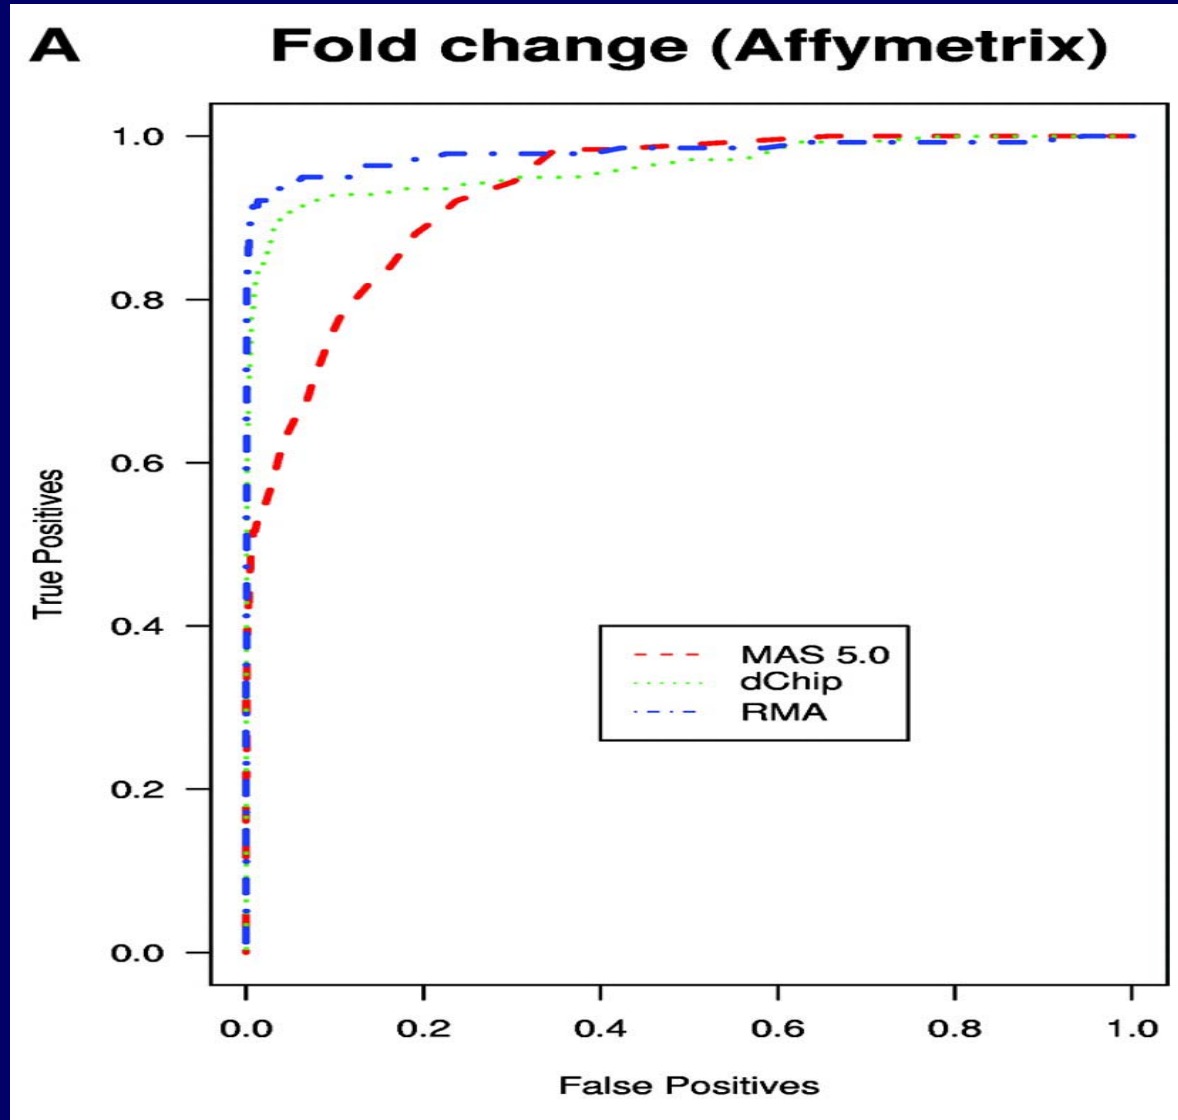

Little effect on Spike-ins

Method	All	Low	Mid	High	FC
No Normalization	0.493 (0.845)	0.185 (0.148)	0.664 (0.733)	0.328 (0.207)	0.484 (0.952)
Quantile	0.493 (0.851)	0.184 (0.153)	0.665 (0.741)	0.329 (0.224)	0.484 (0.955)
Scaling	0.493 (0.852)	0.186 (0.156)	0.663 (0.742)	0.33 (0.225)	0.484 (0.954)

ROC Curves

Comparing Established Expression Measures

Probe Level Models for Detection of Differential Expression

General Probe Level Model

$$y_{ij} = f(\mathbf{X}) + \varepsilon_{ij}$$

- Where $f(\mathbf{X})$ is a linear function of factor (and possibly covariate) variables
- Assume that $E[\varepsilon_{ij}] = 0$

$$\text{Var}[\varepsilon_{ij}] = \sigma^2$$

$$y_{ij} = \log_2 \mathbf{N}\left(\mathbf{B}(PM_{ij})\right)$$

We Will Focus on Two Particular PLM

- Array effect model

$$y_{ij} = \alpha_i + \beta_j + \varepsilon_{ij}$$

- Treatment effect model

$$y_{ij} = \alpha_i + \tau_{l_j} + \varepsilon_{ij}$$

In both cases $\sum_{i=1}^I \alpha_i = 0$

Fitting the PLM

- Robust regression using M-estimation
- By default, we will use Huber's Influence function ψ
- Fitting algorithm is IRLS with weights $\frac{\psi(r)}{r}$
- Software for fitting such models is part of *affyPLM* package of Bioconductor

Variance Covariance Estimates

- Suppose model is $Y = X\beta + \varepsilon$
- Huber (1981) gives three forms for estimating variance covariance matrix

$$\kappa^2 \frac{1/(n-p) \sum_i \psi(r_i)^2}{\left[1/n \sum_i \psi'(r_i)\right]^2} (X^T X)^{-1}$$

$$\kappa \frac{1/(n-p) \sum_i \psi(r_i)^2}{1/n \sum_i \psi'(r_i)} W^{-1}$$

$$\frac{1}{\kappa} 1/(n-p) \sum_i \psi(r_i)^2 W^{-1} (X^T X) W^{-1}$$

We will use this form

$$W = X^T \Psi' X$$

Fold Change

$$FC = \bar{X}_l - \bar{X}_m$$

Where

$$\bar{X}_l = \frac{\sum \beta_j \text{Ind}(j \in \text{group } l)}{\sum \text{Ind}(j \in \text{group } l)}$$

Simple t-statistic

$$t = \frac{\bar{X}_l - \bar{X}_m}{\sqrt{\frac{s_l^2}{n_l} + \frac{s_m^2}{n_m}}}$$

“Robust” t-statistic

$$t = \frac{\tilde{X}_l - \tilde{X}_m}{\sqrt{\frac{\tilde{S}_l^2}{n_l} + \frac{\tilde{S}_m^2}{n_m}}}$$

- Use medians in place of means
- Use MAD in place of standard deviation

Simple Moderated t-Statistic

$$t = \frac{\bar{X}_l - \bar{X}_m}{\sqrt{\frac{s_l^2}{n_l} + \frac{s_m^2}{n_m} + S_{\text{med}}}}$$

- S_{med} is median $\sqrt{\frac{s_l^2}{n_l} + \frac{s_m^2}{n_m}}$ across all genes

Limma “ebayes” t-statistic

- Generalization of Bayesian method of Lonnstadt and Speed (2002) to the general linear model case
- An alternative and much more sophisticated moderated t-statistic
- From the *limma* Bioconductor package.

Probe Level Model test statistics

- Suppose that Σ is component of the variance-covariance matrix related to β
- Let c be the contrast vector defined such that the j th element of c is $1/n_l$ if array j is in group l and $-1/n_m$ if array j is in group m , 0 otherwise

Probe Level Model test statistics

$$t_{\text{PLM.1}} = \frac{\mathbf{c}^T \boldsymbol{\beta}}{\sqrt{\sum_{j=1}^J c_j^2 \Sigma_{jj}}} \quad t_{\text{PLM.2}} = \frac{\mathbf{c}^T \boldsymbol{\beta}}{\sqrt{\mathbf{c}^T \boldsymbol{\Sigma} \mathbf{c}}}$$

A First Comparison

- 8 chips from Affymetrix HG-U95A spike-in dataset
 - 4 arrays for each of two concentration profiles
- Fit an array effect model to all 8 chips
 - Compare the performance of the different methods by looking at all comparisons
 - 1 vs 1
 - 2 vs 2
 - 3 vs 3
 - 4 vs 4

Affy Spikein (4 chips): 1 on 1

Affy Spikein: 2 on 2

Affy Spikein: 3 on 3

Affy Spikein: 4 on 4

What Happens as the Number of Arrays Increases?

- Expand comparison to all 24 Arrays with same concentration profiles from Affymetrix HG-U95A spike-in dataset
- Fit an array effect model to all 24 arrays
- Look at comparisons between equal number of chips

True positives when FP = 0

A Larger Comparison

- Look at the entire 59 chips for Affymetrix HG-U95A spike-in dataset
- Examine two cases. After standard preprocessing
 - Fit a model to all 59 chips
 - Fit models for each pairwise comparison
- There are 91 pairwise comparisons

Results

Method	Individual Models			Single Model		
	0% FP	5% FP	AUC	0% FP	5% FP	AUC
FC	0.451	0.985	0.975	0.444	0.982	0.971

More Spike-in Datasets

- Two GeneLogic Spike-in datasets
 - AML dataset (34 arrays)
 - Tonsil dataset (36 arrays)
- In each case use single models fitted to all arrays

Genelogic Tonsil data

GL AML data

What is going on here?

- Examine residuals stratified by concentration group
 - Spike-ins
 - Randomly chosen non-differential probesets at low, medium and high average expression

GeneLogic AML Spike-ins

GeneLogic Tonsil dataset

How About With More “Real” Data?

- Previous comparisons were for Spike-in data where only 11 or 14 probesets were expected to show any change between conditions. Consider GeneLogic Dilution/Mixture study. Using the 30 Liver and 30 CNS arrays to give a “truth”
- Use the 75:25 (5 arrays) and 25:75 (5 arrays) mixture arrays to test
- Choose 400 probesets with most extreme t-statistics from Dilution set to define “truth”

Results

Method	3 vs 3			4 vs 4			5 vs 5		
	0% FP	5% FP	AUC	0% FP	5% FP	AUC	0% FP	5% FP	AUC

Ebayes	0.001	0.918	0.744	0	0.933	0.761	0	0.943	0.776

What about the treatment effect model?

- The limma ebayes test statistic seems to be outperforming the PLM test statistics in the AUC statistic. Closer examination of ROC curve shows it exceeding all other methods between 0.25% and 2.5% false positives.
- Try the Treatment effect model with
 - PLM.2
 - PLM.2 with a simple moderation

Mixture data: 5 on 5

Ongoing work in this area

- Technology changes: What still works? What doesn't?
- Better moderation for the PLM test statistic
- Other probe-level models (eg Introduce sequence information)

Additional Slides

Background Signal Methods

- Affymetrix
 - Location dependent background based on grids
 - I will refer to this as the MAS 5 background
 - Originally proposed subtracting MM from PM but this is problematic because as many as a third of MM's are greater than the respective PM
 - No longer used
 - Now uses what they refer to as the Ideal Mismatch which is MM when possible and something else when not possible (designed so that there is now no negatives)
 - Call this IMM

Original RMA Background

- Convolution model is suggested by looking at density of observed empirical distributions

Convolution Model

- $O = S + N$
 - O is observed PM, S is signal (assumed exponential), N is noise (assumed normal, truncated at zero)
- Correction is then

$$E(S | O = o) = a + b \frac{\phi\left(\frac{a}{b}\right) - \phi\left(\frac{o-a}{b}\right)}{\Phi\left(\frac{a}{b}\right) - \Phi\left(\frac{o-a}{b}\right) - 1}$$

$$a = o - \mu - \sigma^2 \alpha, b = \sigma$$

A Standard Curve Adjustment Based on Spike-in Information

- Observes that there is a curve that relates observed expression and spike-in concentration. The ideal would be to have a linear relationship between concentration and computed expression. The curve gives us a concentration dependent adjustment

What About Non Spike-ins?

- We don't know a concentration for most probesets. If we did, or if we had a variable that related to concentration, the adjustment would be easy to perform
- Fit the following model

$$y_{1i}^{(k)} = \alpha_i^{(k)} + \varepsilon_i^{(k)}$$

$$y_{2i}^{(k)} = \alpha_i^{(k)} + \gamma^{(k)} + \varepsilon_i^{(k)}$$

- Where $y_{1i}^{(k)} = \log_2 PM_i^{(k)}$
 $y_{2i}^{(k)} = \log_2 MM_i^{(k)}$

γ Relates to Concentration

Establishing a Relationship Between γ and Concentration

The Two Curves Yield an Adjustment Curve

Quantile Normalization

- Normalize so that the quantiles of each chip are equal. Simple and fast algorithm. Goal is to give same distribution to each chip.

- We will illustrate the algorithm with an example.

Sort columns of original matrix

$$\begin{bmatrix} 1 & 5 & 3 & 5 \\ 2 & 1 & 6 & 7 \\ 3 & 2 & 2 & 6 \\ 4 & 6 & 1 & 8 \end{bmatrix} \rightarrow \begin{bmatrix} 1 & 1 & 1 & 5 \\ 2 & 2 & 2 & 6 \\ 3 & 5 & 3 & 7 \\ 4 & 6 & 6 & 8 \end{bmatrix}$$

Take averages across rows

$$\begin{bmatrix} 1 & 1 & 1 & 5 \\ 2 & 2 & 2 & 6 \\ 3 & 5 & 3 & 7 \\ 4 & 6 & 6 & 8 \end{bmatrix} \rightarrow \begin{bmatrix} 2 \\ 3 \\ 4.5 \\ 6 \end{bmatrix}$$

Set average as value for All elements in the row

$$\begin{bmatrix} 2 \\ 3 \\ 4.5 \\ 6 \end{bmatrix} \rightarrow \begin{bmatrix} 2 & 2 & 2 & 2 \\ 3 & 3 & 3 & 3 \\ 4.5 & 4.5 & 4.5 & 4.5 \\ 6 & 6 & 6 & 6 \end{bmatrix}$$

Unsort columns of matrix to original order

$$\begin{bmatrix} 2 & 2 & 2 & 2 \\ 3 & 3 & 3 & 3 \\ 4.5 & 4.5 & 4.5 & 4.5 \\ 6 & 6 & 6 & 6 \end{bmatrix} \rightarrow \begin{bmatrix} 2 & 4.5 & 4.5 & 2 \\ 3 & 2 & 6 & 4.5 \\ 4.5 & 3 & 3 & 3 \\ 6 & 6 & 2 & 6 \end{bmatrix}$$

Why Quantile Normalization?

- Quantile normalization found to perform acceptably in reducing variance without drastic bias effects
- Quantile normalization is fast

RMA Model

- To each probeset (k), with i being number of probes and j being number of chips, fit the model:

$$y_{ij}^{(k)} = \alpha_i^{(k)} + \beta_j^{(k)} + \varepsilon_{ij}^{(k)}$$

where $\alpha_i^{(k)}$ is a probe effect and $\beta_j^{(k)}$ is the log gene expression. $y_{ij}^{(k)}$ is the log2 background adjusted and normalized PM intensity

- Different ways to fit this model
 - Median polish – quick
 - Robust linear model – yields some good quality diagnostic tools

Probe Level Models are based on RMA

- RMA method
 - Convolution Model Background
 - Quantile Normalization
 - Summarization using a robust multi-chip model on the log scale. Model is fitted using the median polish algorithm on a probeset by probeset basis

Pseudo-chip Images using PLM outputs aid QC

2353p99hpp_av08.col

2353p99hpp_av08.col

2353p99hpp_av08.col

Basic RMA model

Let $y_{ij} = \log_2 N(B(PM_{ij}))$

then $y_{ij} = m + \alpha_i + \beta_j + \varepsilon_{ij}$

where α_i is probe-effect

β_j is chip-effect ($m + \beta_j$ is log2 gene expression on array j)

Median-polish imposes constraints

$$\text{median}_i \alpha_i = \text{median}_j \beta_j = 0$$

$$\text{median}_i \varepsilon_{ij} = \text{median}_j \varepsilon_{ij} = 0$$

Advantages/Disadvantages of RMA/Median polish

- Advantages
 - Fast
 - Gene expression measures perform favorably when compared with MAS 5.0, Li-Wong MBEI
 - Robust against outliers
- Disadvantages
 - No standard error estimates
 - No algorithmic flexibility to fit alternative models
